- They modified members of Daubechies orthogonal family to perform the task.
- Start with compactly supported and continuous scaling function ϕ

$$\phi(t) = \sum_{k=0}^{N} h_k \phi(2t-k)$$

and assume it generates a Multiresolution Analysis (MRA) for $L^2(\mathbb{R})$.

• ϕ and its integer translates form a partition of unity:

$$\sum_{k} \phi(t-k) = 1$$

• Construct $P_r(t)$, 0 < r < 1 as follows:

$$P_r(t) = \sum_{n \in \mathbb{Z}} r^{|n|} \phi(t-n)$$

• Construct $P_r(t)$, 0 < r < 1 as follows:

$$P_r(t) = \sum_{n \in \mathbb{Z}} r^{|n|} \phi(t-n)$$

• We can compute the Fourier transform of $P_r(t)$:

$$\hat{P}_r(\omega) = \frac{1 - r^2}{1 - 2r\cos\omega + r^2}\hat{\phi}(\omega)$$

► $P_r(t) \ge 0$, $P_r \in V_0$

$$\blacktriangleright P_r(t) \ge 0, \qquad P_r \in V_0$$

 \triangleright *P_r* solves a dilation equation.

$$P_r(t) = \sum_k a_k P_r(2t-k),$$

where

$$a_{k} = \sum_{n} h_{k-2n} r^{|n|} \frac{1+r^{2}}{1-r^{2}} - \frac{r^{|n|+1}}{1-r^{2}} (h_{k-1-2n} + h_{k+1-2n}).$$

In this case, Φ satisfies a matrix refinement equation

$$\Phi(t) = \sum_{k} C_k \Phi(2t-k)$$

Here C_k are $A \times A$ matrices.

We further assume that:

In this case, Φ satisfies a matrix refinement equation

$$\Phi(t) = \sum_{k} C_k \Phi(2t-k)$$

Here C_k are $A \times A$ matrices.

- We further assume that:
 - ► Each φ^ℓ is compactly supported on [0, M_ℓ], M_ℓ ∈ Z₊ and continuous.

In this case, Φ satisfies a matrix refinement equation

$$\Phi(t) = \sum_{k} C_k \Phi(2t-k)$$

Here C_k are $A \times A$ matrices.

- We further assume that:
 - ► Each φ^ℓ is compactly supported on [0, M_ℓ], M_ℓ ∈ Z₊ and continuous.
 - There is a vector $\mathbf{c} = (c_1, \dots, c_A)^T$ for which

$$\sum_{\ell=1}^{A}\sum_{k}c_{\ell}\phi^{\ell}(t-k)=\sum_{k}\mathbf{c}\cdot\Phi(t-k)=1$$

This is the partition of unity condition.

Finally, we assume that Φ has polynomial accuracy *m*. That is, there exist constants f_{nk}^{ℓ} such that for n = 0, 1, ..., m - 1, we have

$$t^{n} = \sum_{\ell=1}^{A} \sum_{k} f_{nk}^{\ell} \phi^{\ell}(t-k) = \sum_{k} \mathbf{f}_{nk} \cdot \Phi(t-k)$$

Note that from the previous slide

$$1 = t^0 = \sum_k \mathbf{c} \cdot \Phi(t-k) = \sum_k \mathbf{f}_{0k} \cdot \Phi(t-k)$$

so that $\mathbf{c} = \mathbf{f}_{0k}$ for all $k \in \mathbb{Z}$.

The results of Walter and Shen can be extended to scaling vectors
 Φ with only a modest condition on the partition of unity coefficients
 c of Φ.

- The results of Walter and Shen can be extended to scaling vectors
 Φ with only a modest condition on the partition of unity coefficients
 c of Φ.
- Moreover, the construction can be altered so that compact support can be retained - that's the contribution of using scaling vectors.

Let $\Phi = (\phi^1, \dots, \phi^A)$. We say Φ satisfies Condition B if for some $j \in \{1, 2, \dots, A\}, \phi^j(t) \ge 0$ for $t \in \mathbb{R}$ and there exist finite index sets Λ_i and constants c_{ik} for $i \ne j$ such that:

(B1)
$$\tilde{\phi}^{i}(t) := \phi^{i}(t) + \sum_{k \in \Lambda_{i}} c_{ik} \phi^{j}(t-k) \ge 0, t \in \mathbb{R}.$$

(B2) $d_{j} := c_{j} - \sum_{i \neq j} \sum_{k \in \Lambda_{i}} c_{i} c_{ik} \ge 0,$
(B3) $c_{i} \ge 0$, for $i \neq j$.

Here $\mathbf{c} = (c_1, \ldots, c_A)^T$ are the coefficients that form the partition of unity for Φ :

$$1 = \sum_{k} \mathbf{c} \cdot \Phi(t-k)$$

THURSDAY, 20.9.2012 (14:00-14:30)

Theorem. (D. Ruch, PVF) Suppose the scaling vector

$$\Phi = (\phi^1, \phi^2, \dots, \phi^A)^T$$

is bounded, compactly supported, has polynomial accuracy $m \ge 1$, and satisfies Condition B. Then the nonnegative scaling vector

$$\tilde{\Phi} = (\tilde{\phi}^1, \dots, \tilde{\phi}^{j-1}, \phi^j, \tilde{\phi}^{j+1}, \dots \tilde{\phi}^A)^T$$

is a bounded, compactly supported scaling vector with accuracy $m \ge 1$ that generates the same MRA as Φ .

Outline of Proof. The proof is constructive. WLOG assume j = A.

THURSDAY, 20.9.2012 (14:00-14:30)

SUMMER SCHOOL, INZELL

Outline of Proof. The proof is constructive. WLOG assume j = A.

Build *M*(*z*) to be an upper triangular matrix, with ones on the main diagonal and ∑_{k∈Λi} c_{ik}z^k in the *i*, *j* position (*i* < *j*). Here z = e^{-iω}.

∃ → < ∃ →</p>

Outline of Proof. The proof is constructive. WLOG assume j = A.

- Build *M*(*z*) to be an upper triangular matrix, with ones on the main diagonal and ∑_{k∈Λi} c_{ik}z^k in the *i*, *j* position (*i* < *j*). Here z = e^{−iω}.
- The vector that works is

$$ilde{\Phi} = \mathcal{F}^{-1}\left(M(z)\hat{\Phi}(z)\right)$$

∃ → < ∃ →</p>

Example. Recall the DGHM example.

- $\phi^1(t) \geq 0$.
- supp $(\phi^1) = [0, 1]$ and supp $(\phi^2) = [0, 2]$.
- ϕ^1 , ϕ^2 are continuous and have polynomial accuracy m = 2.
- the partition of unity coefficients are

$$c_1 = (1 + \sqrt{2})^{-1}$$
 and $c_2 = \sqrt{2}c_1$.

We take the index set $\Lambda_2 = \{0, 1\}$ with $c_{20} = c_{21} = \frac{1}{2}$ so that

$$\tilde{\phi}^2 = \phi^2(t) + \frac{1}{2}\phi^1(t) + \frac{1}{2}\phi^1(t-1)$$

The new partition of unity coefficients are

$$egin{aligned} d_1 &= c_1 > 0 \ d_2 &= c_2 - c_1 \left(c_{20} + c_{21}
ight) > 0 \end{aligned}$$

THURSDAY, 20.9.2012 (14:00-14:30)

Suppose $\Phi(t) = \left(\phi^1(t), \phi^2(t), \dots, \phi^A(t)\right)^T$

▶ Compact support: supp $(\phi^i) = [0, M_i], M_i \in \mathbb{Z}_+$.

Suppose $\Phi(t) = \left(\phi^1(t), \phi^2(t), \dots, \phi^A(t)\right)^T$

• Compact support: supp $(\phi^i) = [0, M_i], M_i \in \mathbb{Z}_+$.

• • • satisfies a finite-length matrix refinement equation:

$$\Phi(t) = \sum_{k=0}^{N} C_k \Phi(2t-k)$$

Suppose $\Phi(t) = \left(\phi^1(t), \phi^2(t), \dots, \phi^A(t)\right)^T$

- Compact support: supp $(\phi^i) = [0, M_i], M_i \in \mathbb{Z}_+$.
- • satisfies a finite-length matrix refinement equation:

$$\Phi(t) = \sum_{k=0}^{N} C_k \Phi(2t-k)$$

Each φⁱ(t) is continuous and Φ achieves polynomial accuracy m ≥ 1. That is, for n = 0,..., m − 1 we can write

$$t^n = \sum_{\ell=1}^{A} \sum_{k} f_{nk}^{\ell} \phi^{\ell}(t-k) = \sum_{k} \mathbf{f}_{nk} \cdot \Phi(t-k)$$

🐺 University of St. Thomas

(日)

Suppose $\Phi(t) = (\phi^{1}(t), \phi^{2}(t), ..., \phi^{A}(t))^{T}$

- Compact support: supp $(\phi^i) = [0, M_i], M_i \in \mathbb{Z}_+.$
- • satisfies a finite-length matrix refinement equation:

$$\Phi(t) = \sum_{k=0}^{N} C_k \Phi(2t-k)$$

Each φⁱ(t) is continuous and Φ achieves polynomial accuracy m ≥ 1. That is, for n = 0,..., m − 1 we can write

$$t^n = \sum_{\ell=1}^{A} \sum_{k} f_{nk}^{\ell} \phi^{\ell}(t-k) = \sum_{k} \mathbf{f}_{nk} \cdot \Phi(t-k)$$

• Φ generates an MRA for $L^2(\mathbb{R})$.

► We will construct the left edge functions for V₀[0,∞). The right edge functions follow analogously.

< □ > < 同

- ► We will construct the left edge functions for V₀[0,∞). The right edge functions follow analogously.
- For $\ell = 1, ..., A$, suppose that the set *S* of non-zero functions

$$\boldsymbol{\mathcal{S}} = \left\{ \overline{\phi}_k^\ell(t)
ight\}_{k \in \mathbb{Z}}$$

where

$$\overline{\phi}_{k}^{\ell}(t) = \phi^{\ell}(t-k)\big|_{[0,\infty)}$$

are linearly independent and let n(S) be the number of elements in *S*.

- ► We will construct the left edge functions for V₀[0,∞). The right edge functions follow analogously.
- For $\ell = 1, ..., A$, suppose that the set S of non-zero functions

$$S = \left\{ \overline{\phi}_k^\ell(t)
ight\}_{k \in \mathbb{Z}}$$

where

$$\overline{\phi}_{k}^{\ell}(t) = \phi^{\ell}(t-k)\big|_{[0,\infty)}$$

are linearly independent and let n(S) be the number of elements in *S*.

 S is simply the right shifts of φ^ℓ and the left shifts for k = 1,..., M_ℓ − 1. Here, [0, M_ℓ] is the support of φ^ℓ.

<ロ> <同> <同> <同> < 同> < 同> < 同> < 同

We define the left edge functions $\phi_{L,n}$ by

$$\phi_{L,n}(t) = \sum_{\ell=1}^{A} \sum_{k=1-M_{\ell}}^{0} \mathbf{f}_{nk}^{\ell} \overline{\phi}_{k}^{\ell}(t)$$

We have

$$\phi_{L,n}(t) = t^n \quad \text{on} \quad [0,1]$$

We are building the edge function by simply taking those $\overline{\phi}_{k}^{\ell}(t)$ that contribute to t^{n} on [0, 1].

Proposition. The $\phi_{L,n}(t)$ satisfy a matrix refinement equation.

The proof is straightforward and you end up with

$$\phi^{L,n}(t) = 2^{-n}\phi_{L,n}(2t) + \sum_{j=2-2M_n}^{N} \mathbf{q}_{nj}\Phi(2t-j)$$

for each $n = 0, 1, \ldots, m - 1$, where

$$\mathbf{q}_{nj} = \begin{cases} \sum_{k=1-M_n}^{0} \mathbf{f}_{nk} C_{j-2k} - 2^{-n} \mathbf{f}_{nj}, & j \in \{1 - M_n, \dots, 0\} \\ \sum_{k=1-M_n}^{0} \mathbf{f}_{nk} C_{j-2k}, & j \in \{2 - 2M_n, \dots, -M_n\} \cup \{1, \dots, N\} \end{cases}$$

TUNIVERSITY of ST. THOMAS

< 口 > < 回 > < 回 > < 回 > < 回 > -

Example. Recall the DGHM example.

•
$$\phi_1^1(t) \ge 0, M_1 = 1, M_2 = 2.$$

- ▶ ϕ^1 , ϕ^2 are continuous and have polynomial accuracy m = 2.
- the partition of unity coefficients are

$$\mathbf{f}_{00} = \left(\frac{1}{1+\sqrt{2}}, \frac{\sqrt{2}}{1+\sqrt{2}}\right)^{T}.$$

$$\mathbf{S} = \left\{\phi^{1}(t), \overline{\phi}^{2}(t), \overline{\phi}^{2}(t+1)\right\}.$$

We can easily write down the formula for the edge function (noting that $f_{0,k}^{\ell} = f_{0,0}^{\ell}$ for all $k \in \mathbb{Z}$):

THURSDAY, 20.9.2012 (14:00-14:30)

SUMMER SCHOOL, INZELL

13/17

If we want a nonnegative edge function, then we need to use the scaling vector:

Here,

$$\mathbf{f}_{00} = (\mathbf{c}_1, \mathbf{c}_2 - \mathbf{c}_1)^T = \left(\frac{1}{1 + \sqrt{2}}, 3 - 2\sqrt{2}\right)^T$$

🐺 University of St. Thomas

The resulting edge function:

Example. G. Plonka and V. Strela used a two-scale similarity transform in the frequency domain to construct the scaling vector

$$\Phi(t) = \sum_{k=0}^{2} C_k \cdot \Phi(2t-k)$$

- Φ and its translates are not orthogonal.
- Φ is continuous and has approximation order m = 3.

•
$$M_1 = M_2 = 2$$
.

- Partition of unity: $f_{0,0} = (0, 1)^T$.
- We also need $\mathbf{f}_{1,0} = \left(\frac{1}{6}, 1\right)^T$.

< 口 > < 回 > < 回 > < 回 > < 回 > -

We use the scaling vector

SUMMER SCHOOL, INZELL

큰

▶ < ≣ >

We can write down the (nonnegative!) edge functions:

Theorem. (**D. Ruch**, **PVF**) For some index set *B*, let {*L_i*} be a finite set of left edge functions with support $[0, \delta_i]$ and assume that $\{L_i, \phi^{\ell}(\cdot - k)\}_{i,\ell,k\geq 0}$ is a linearly independent set. Then $\{L_i(2^j \cdot), \phi^{\ell}(2^j \cdot - k)\}_{i,\ell,k\geq 0}$ is a Riesz basis for *V_j*, where $L^2[0, \infty) = \overline{\cup_j V_j}$.

► The DGHM scaling vector has polynomial accuracy m = 2, yet we only constructed the edge function φ_{L,0}(t) (1 on [0, 1].

- ► The DGHM scaling vector has polynomial accuracy m = 2, yet we only constructed the edge function φ_{L,0}(t) (1 on [0, 1].
- ▶ The Plonka/Strela scaling vector has polynomial accuracy m = 3, yet we only constructed the edge functions $\phi_{L,0}(t)$ (1 on [0, 1]) and $\phi_{L,1}(t)$ (t on [0, 1]).

- ► The DGHM scaling vector has polynomial accuracy m = 2, yet we only constructed the edge function φ_{L,0}(t) (1 on [0, 1].
- ▶ The Plonka/Strela scaling vector has polynomial accuracy m = 3, yet we only constructed the edge functions $\phi_{L,0}(t)$ (1 on [0, 1]) and $\phi_{L,1}(t)$ (t on [0, 1]).
- In both cases it seems we are missing an edge function φ_{L,1}(t) for DGHM and φ_{L,2}(t) for Plonka/Strela.

- ► The DGHM scaling vector has polynomial accuracy m = 2, yet we only constructed the edge function φ_{L,0}(t) (1 on [0, 1].
- ▶ The Plonka/Strela scaling vector has polynomial accuracy m = 3, yet we only constructed the edge functions $\phi_{L,0}(t)$ (1 on [0, 1]) and $\phi_{L,1}(t)$ (t on [0, 1]).
- In both cases it seems we are missing an edge function φ_{L,1}(t) for DGHM and φ_{L,2}(t) for Plonka/Strela.
- But it turns out that we don't need them in both cases we were able to find constants α_i so that

$$\sum_{j=0}^{m-2} \alpha_j \phi_{L,j}(t) + \sum_{j=1}^{2} \alpha_j + m - 2\overline{\phi}^j(t-k) = t^{m-1}$$

on [0, 1]. (Here, m = 2 for DGHM and m = 3 for Plonka/Strela).

THURSDAY, 20.9.2012 (14:00-14:30)

on [0, 1].

► Rewriting using the linearly independent \$\overline{\sigma}_k^l(t)\$ and the definition of the edge functions gives the following system:

$$\sum_{j=0}^{m-A} \alpha_j \left[\sum_{\ell=1}^{A} \sum_{k=1-M_\ell}^{0} f_{j,k}^\ell \overline{\phi}_k^\ell(t) \right] + \sum_{\ell=1}^{A} \alpha_{\ell+m-A} \overline{\phi}_0^\ell(t) = \sum_{\ell=1}^{A} \sum_{k=1-M_\ell}^{0} f_{m-1,k}^\ell \overline{\phi}_k^\ell(t)$$

• This system can be rewritten in the form $M\alpha = \mathbf{b}$ where

$$M = \left[\begin{array}{cc} Q & 0 \\ R & I \end{array} \right]$$

Here, *M* has dimension $(m + 1) \times (m + 1)$, *I* is the $A \times A$ identity matrix, and *Q* is an $(m - A + 1) \times (m - A + 1)$ matrix.

• This system can be rewritten in the form $M\alpha = \mathbf{b}$ where

$$M = \left[\begin{array}{cc} Q & 0 \\ R & I \end{array} \right]$$

Here, *M* has dimension $(m + 1) \times (m + 1)$, *I* is the $A \times A$ identity matrix, and *Q* is an $(m - A + 1) \times (m - A + 1)$ matrix.

• Certainly if *Q* is nonsingular, our assertion holds.

We can further refine Q. If we set

$$E_k^\ell = \begin{bmatrix} f_{0,k}^\ell & f_{1,k}^\ell & f_{2,k}^\ell & \cdots & f_{m-2,k}^\ell \end{bmatrix}$$

then we can write Q as

A lemma due to G. Strang says that

$$f_{j,k+1}^{\ell} = \sum_{i=0}^{j} {j \choose i} f_{i,j}^{\ell}$$

We can reformulate this lemma in terms of our rows E^ℓ_k and the upper triangular Pascal matrix

$$P_U = \begin{bmatrix} 1 & 1 & 1 & 1 & \cdots \\ 0 & 1 & 2 & 3 & \cdots \\ 0 & 0 & 1 & 3 & \cdots \\ 0 & 0 & 0 & 1 & \cdots \\ \vdots & \vdots & & \vdots \end{bmatrix}$$

THURSDAY, 20.9.2012 (14:00-14:30)

17/17

In terms of the Pascal matrix, Strang's lemma says

$$E_{k+1}^{\ell} = E_k^{\ell} P_U = \dots = E_1^{\ell} P_U^{k-1} = E_0^{\ell} P_U^k$$

or

$$E_{k+1}^{\ell}P_{U}^{-k} = E_{k}^{\ell}P_{U}^{-k+1} = \dots = E_{1}^{\ell}P_{U}^{-1} = E_{0}^{\ell}$$

э

In terms of the Pascal matrix, Strang's lemma says

$$E_{k+1}^{\ell} = E_k^{\ell} P_U = \cdots = E_1^{\ell} P_U^{k-1} = E_0^{\ell} P_U^k$$

or

$$E_{k+1}^{\ell}P_{U}^{-k} = E_{k}^{\ell}P_{U}^{-k+1} = \dots = E_{1}^{\ell}P_{U}^{-1} = E_{0}^{\ell}$$

▶ Then *Q* becomes

∃→ < ∃→</p>

It is not clear that Q is always nonsingular. It would seem there needs to be conditions placed on the E^ℓ₀.

▶ < ∃ >

- It is not clear that Q is always nonsingular. It would seem there needs to be conditions placed on the E^ℓ₀.
- ▶ In the case where $M_1 = L > 1$ and $M_k = 1, k = 2, ..., A$, (DGHM, for example) we can reduce Q to

$$Q = \begin{bmatrix} E_0^1 P_U^{-1} \\ E_0^1 P_U^{-2} \\ \vdots \\ E_0^1 P_U^{1-L} \end{bmatrix}$$

THURSDAY, 20.9.2012 (14:00–14:30)

SUMMER SCHOOL, INZELL
Using the lower triangular Pascal matrix ($P_L = P_U^T$), we can write Q =

$$\begin{bmatrix} E_{0}^{1}P_{U}^{-1} \\ E_{0}^{1}P_{U}^{-2} \\ \vdots \\ E_{0}^{1}P_{U}^{1-L} \end{bmatrix} = \begin{bmatrix} E_{0}^{1} \\ E_{0}^{1}P_{U}^{-1} \\ \vdots \\ E_{0}^{1}P_{U}^{2-L} \end{bmatrix} P_{U}^{-1} = P_{L} \begin{pmatrix} P_{L}^{-1} \begin{bmatrix} E_{0}^{1} \\ E_{0}^{1}P_{U}^{-1} \\ \vdots \\ E_{0}^{1}P_{U}^{2-L} \end{bmatrix} P_{U}^{-1} \end{pmatrix}$$
$$= P_{L} \begin{pmatrix} \begin{bmatrix} E_{0}^{1} \\ E_{0}^{1} (P_{U}^{-1} - I) \\ E_{0}^{1} (P_{U}^{-1} - I)^{2} \\ \vdots \\ E_{0}^{1} (P_{U}^{-1} - I)^{L-2} \end{bmatrix} P_{U}^{-1} \end{pmatrix} = L \cdot U$$

😨 UNIVERSITY of ST. THOMAS

The first matrix is lower triangular with determinant 1 while the second matrix is upper triangular with determinant Cf¹_{0,0}, C > 0. So if f¹_{0,0} ≠ 0, our matrix Q is nonsingular in this case.

- The first matrix is lower triangular with determinant 1 while the second matrix is upper triangular with determinant Cf¹_{0,0}, C > 0. So if f¹_{0,0} ≠ 0, our matrix Q is nonsingular in this case.
- ► This is certainly the case for the DGHM scaling vector as $f_{0,0}^1 = (1 + \sqrt{2})^{-1}$.
