Radial Kernels via Scale Derivatives and Wavelets

Elena Volontè
Outline

1. New radial kernels
   - Definitions and general results
   - Derivatives
   - Laplacian
   - Examples

2. Wavelets
   - Continuous wavelets transform
   - Discrete wavelets transform
Radial kernels are suited for sparse multivariate interpolation problems

\[ \mathcal{K}(x, y) = \Phi(x - y) = \phi(\|x - y\|_2) =: f(\|x - y\|_2^2 / 2) \quad x, y \in \mathbb{R}^d \]

with a scalar function \( \phi : [0, +\infty) \rightarrow \mathbb{R} \).

**Properties:**
- Radial symmetry,
- Dimension free,
- Invariant under affine transformations.

**Examples** of well-known kernels in literature:
- Gaussian,
- Multiquadrics,
- Whittle-Matérn functions,
- Wendland functions,
- Polyharmonics,
- ...

Elena Volontè
The $d$-variate Fourier transform $\hat{\Phi}$ is radial again and coincides with the Hankel transform using the $f$-form of the kernel

$$\hat{\Phi}(\omega) = \hat{f} \left( \frac{\|\omega\|^2}{2} \right),$$

with

$$\hat{f}(t) := \int_{0}^{\infty} f(s)s^{\nu} h_{\nu}(st)ds, \quad f(s) = \int_{0}^{\infty} \hat{f}(t)t^{\nu} h_{\nu}(ts)dt,$$

and $h_{\nu}(z^2/4) := (z/2)^{-\nu} J_{\nu}(z)$, $J_{\nu}$ Bessel function of the first kind and $\nu = (d - 2)/2$.

**Theorem**

*Let $\Phi$ be a continuous function in $L^1(\mathbb{R}^d)$. $\Phi$ is strictly positive definite if and only if $\Phi$ is bounded and its Fourier transform is non-negative and not identically equal to zero.*
The main ideas in [Bozzini, Rossini, Schaback, V. '15] are:

- to introduce a scaling $z \in \mathbb{R}^+$ in the transform

$$\hat{f}(\cdot z)(u) = z^{-\nu-1}\hat{f}(\cdot)(u/z)$$

- to consider a functional $\lambda^z$ that act linearly respect to $z$ and commute with integrals

$$(\lambda^z f(\cdot z))^\wedge(u) = \lambda^z (z^{-\nu-1} \hat{f}(u/z))$$

As a linear functional $\lambda$ we take the $k$–th derivative respect to $z$

$$\lambda^z f(z) = \frac{d^k}{dz^k} f(z),$$

so the previous relation becomes

$$\left( \frac{d^k}{dz^k} f(\cdot z) \right)^\wedge(u) = \left( f^{(k)}(\cdot z)(\cdot)^k \right)^\wedge(u) = \frac{d^k}{dz^k} \left( z^{-\nu-1} \hat{f}(\cdot)(u/z) \right)$$
We specialise to the first derivative $k = 1$

\[
(tf'(tz))^\wedge (u) = \frac{d}{dz} \left( z^{-\nu-1} \hat{f}(\cdot)(u/z) \right)
\]

Moreover if we consider $z = 1$ we have

\[
(tf'(t))^\wedge (u) = \frac{d}{dz} \bigg|_{z=1} \left( z^{-\nu-1} \hat{f}(\cdot)(u/z) \right)
\]

In the following we define the new kernels $\psi$ as the right term and its Fourier transform $\hat{\psi}$ the function in the left term.

With this choice and using the previous cited Theorem we will see that new kernels are positive definite.
We consider classes of kernels $\Phi$ that are closed under taking derivatives in $f$-form

$$f_p'(s) = c(p)f_{D(p)}(s)$$

where $s = \|x - y\|^2/2$ and the parameter $p$ in the definition of the kernel $\Phi$ goes to a new parameter $D(p)$, moreover there is a factor $c(p)$.

**Theorem**

The transition $\Phi \rightarrow -\Delta \Phi$ on radial kernels generates a radial kernel consisting of a weighted sum

$$-\Delta^x \Phi(x - y) = -\|x - y\|^2 f'' \left( \frac{\|x - y\|^2}{2} \right) - df' \left( \frac{\|x - y\|^2}{2} \right)$$

of two radial kernels, if $f$ is the $f$-form of $\Phi$, and if the action of $-\Delta$ is valid on the kernel. If, furthermore, the class of kernels is invariant under taking derivatives of $f$-forms, then the resulting kernel is a weighted linear combination of two radial kernels of the same family.
**Theorem**

For all classes of radial kernels that are closed under taking derivatives in f–form, the procedure with derivatives generates kernels that are images of the negative Laplacian applied to Fourier transforms of kernels of the same class.

**Proof.**

Using that the radial kernels is closed under taking derivatives and

\[ t f(t) = \frac{\|x\|^2}{2} \Phi(\|x\|) = \frac{1}{2}(-\Delta \hat{\Phi})^\vee(\|x\|), \]

we have

\[ (t f'_p(t))^\wedge(\|\omega\|^2/2) = c(p) (t f_{D(p)}(t))^\wedge(\|\omega\|^2/2) = -\frac{c(p)}{2} \Delta \hat{\Phi}_{D(p)}(\|\omega\|). \]
New kernels

We have

\[ c(p) \left( t f_{D(p)}(t) \right)^\wedge (\|\omega\|_2^2/2) = -\frac{c(p)}{2} \Delta \hat{\Phi}_{D(p)}(\|\omega\|_2) \]

\[ = -\frac{c(p)}{2} \left( \|\omega\|^2 \hat{f}_{D(p)}'' \left( \frac{\|\omega\|^2}{2} \right) + d \hat{f}_{D(p)}' \left( \frac{\|\omega\|^2}{2} \right) \right) \]

We define the new kernel and its Fourier transform

\[ \psi(x) = -\frac{\|x\|^2}{2} \hat{f}_{D(p)}'' \left( \frac{\|x\|^2}{2} \right) - \frac{d}{2} \hat{f}_{D(p)}' \left( \frac{\|x\|^2}{2} \right) \]

\[ \hat{\psi}(\omega) = \frac{\|\omega\|^2}{2} f_{D(p)} \left( \frac{\|\omega\|^2}{2} \right) \]

The Fourier transform \( \hat{\psi} \) is non negative and not identically zero because \( f_{D(p)} \) is positive definite, then the function \( \psi \) is positive definite.
“New” Gaussian kernels

\[
\phi_G(x) = \exp(-\|x\|^2 / 2)
\]
\[
\hat{\phi}_G(\omega) = \exp(-\|\omega\|^2 / 2)
\]
\[
\psi_G(x) = (d/2 - \|x\|^2) \exp(-\|x\|^2 / 2)
\]
\[
\hat{\psi}_G(\omega) = \frac{\|\omega\|^2}{2} \exp(-\|\omega\|^2 / 2)
\]

It’s not new because, for \( d = 2 \), it is the Mexican hat.
New inverse multiquadrics kernels

For $\beta > d/2 + 1$

$$\phi_m(x) = (1 + \|x\|^2)^{-\beta}$$
$$\hat{\phi}_m(\omega) = \frac{2^{1-\beta}}{\Gamma(\beta)} \|\omega\|^{\beta-d/2} K_{\beta-d/2}(\|\omega\|)$$

$$\psi_m(x) = \frac{2^{-\beta}}{\Gamma(\beta)} \left[ d \|x\|^{\beta-d/2} K_{\beta-d/2}(\|x\|) - \|x\|^{\beta-d/2+1} K_{\beta-d/2-1}(\|x\|) \right]$$
$$\hat{\psi}_m(\omega) = \beta \|\omega\|^2 (1 + \|\omega\|^2)^{-\beta-1}$$
New Whittle-Matérn kernels

For $\beta > d/2 + 1$

$$\phi_M(x) = \frac{2^{1-\beta}}{\Gamma(\beta)} \|x\|^{\beta-d/2} K_{\beta-d/2}(\|x\|)$$

$$\hat{\phi}_M(\omega) = (1 + \|\omega\|^2)^{-\beta}$$

$$\psi_M(x) = \frac{d}{2} (1 + \|x\|^2)^{-\beta}$$

$$- \beta \|x\|^2 (1 + \|x\|^2)^{-\beta-1}$$

$$\hat{\psi}_M(\omega) = \frac{2^{-\beta}}{\Gamma(\beta)} \|\omega\|^{\beta-d/2+1} K_{\beta-d/2-1}(\|\omega\|)$$
Wavelets

We analyse the properties of the new kernels. They have a good decay

\[ \left| \hat{\psi}(\omega) \right| = O(\|\omega\|^\alpha) \quad \|\omega\| \to 0, \text{ for } \alpha \geq 2 \]
\[ \left| \hat{\psi}(\omega) \right| = O(\|\omega\|^{-\gamma}) \quad \|\omega\| \to +\infty, \text{ for } \gamma > d + 2 \]

From the construction with derivatives we have

\[ \hat{\psi}(\omega) = \|\omega\|^2 \phi(\omega), \]

\( \phi(\omega) \) is bounded, since it is positive definite, so

\[ \hat{\psi}(0) = 0 = \int_{\mathbb{R}^d} \psi(x) \, dx. \]

The new kernels \( \psi \in N_K := \{\psi_G, \psi_m, \psi_M\} \) are wavelets.
All $\psi \in N_K$ are such that $\psi \in L^1(\mathbb{R}^2) \cap L^2(\mathbb{R}^d)$.

Moreover they satisfy

\[ \int_0^{+\infty} \frac{\left| \hat{\psi}(a\omega) \right|^2}{a} \, da = C_\psi, \quad \forall \omega \neq 0 \text{ and } 0 < C_\psi < +\infty \]

We compute the constant for each $\psi \in N_K$

\[ C_{\psi_G} = \frac{1}{8}, \quad C_{\psi_m} = \frac{\beta}{8\beta + 4}, \quad C_{\psi_M} = \frac{4^{-1-\beta} \sqrt{\pi} \Gamma(2\beta - d) \Gamma(1 + \beta - d/2)}{\Gamma^2(\beta) \Gamma(3/2 + \beta - d/2)} \]

The admissibility condition allows us to recover a function $f \in L^2(\mathbb{R}^d)$ by the set of its wavelets coefficients.
Continuous wavelets transform

Let

$$\psi_{a,b}(x) = a^{-d} \psi \left( \frac{x - b}{a} \right), \ a \in \mathbb{R}^+, \ b \in \mathbb{R}^d$$

The wavelet coefficients of $f$ are the inner product

$$c(a, b) = (f, \psi_{a,b})_{L^2(\mathbb{R}^d)} = \left( f, a^{-d} \psi((\cdot - b)/a) \right)_{L^2(\mathbb{R}^d)}$$

and they give all the important information about the signal.

Due to the admissibility condition we can reconstruct a function $f$ with the wavelet continuous transform

$$f(x) = \frac{1}{C_{\psi}} \int_0^{+\infty} \int_{\mathbb{R}^d} c(a, b) \psi_{a,b}(x) \, db \, \frac{da}{a}$$
Numerical examples

Signal

Coefficients $c(a,b)$ for $\psi_m$ and $\beta = 1.6$

Coefficients $c(a,b)$ for $\bar{\psi}_m$ and $\beta = 1.6$
Discrete wavelets transform

It is interesting to consider discrete case with shift \( k \in \mathbb{Z}^d \) and refinement matrix \( M \), usually \( M = 2I \).

Remark ([Ron, Shen '97])

The function \( \psi \) whose Fourier transform is positive a.e. cannot generate tight frames of the form \( \psi(2^j \cdot -k) \).

For our \( \psi \in N_K \) we can not consider the classical construction of tight frames in the stationary case, we refer to a non-stationary setting.

Let \( M = 2I \) we can define

\[
\hat{\psi}_j(\omega) = \frac{\hat{\psi}(\omega)}{\sqrt{\sigma_j(\omega)}}, \quad \text{where} \quad \sigma_j(\omega) := \sum_{k \in \mathbb{Z}^d} \left| \hat{\psi}(\omega + 2^{j+1} \pi k) \right|^2
\]

is a \( 2^{j+1} \pi \) periodic function.
Wavelet generators

With $M = 2I$ we have to consider $2^d - 1$ cosets and the set

$$\{\psi_j^{(\ell)}(\cdot - 2^{-j}k), \ j \in \mathbb{Z}, \ k \in \mathbb{Z}^d, \ \ell = 1, \ldots, 2^d - 1\}.$$  

We call

$$W_j := \text{span}\{\psi_j^{(\ell)}(\cdot - 2^{-j}k), \ k \in \mathbb{Z}^d, \ \ell = 1, \ldots, 2^d - 1\}$$

we want that $\bigcup_j W_j$ is dense in $L^2(\mathbb{R}^d)$ so $\psi_j^{(\ell)}$ are generators of $L^2(\mathbb{R}^d)$.

For this set of functions we have to show that they satisfy

**Frequency localization property**

Given a compact set $K \subset \mathbb{R}^d \setminus \{0\}$ and $\varepsilon > 0$, there exists $N \in \mathbb{N}$ s.t.

$$\sum_{j > N} \sup_{\omega \in K} |\hat{\psi}_j^{(\ell)}(\omega)|^2 < \varepsilon \quad \text{and} \quad \sum_{j < -N} \sup_{\omega \in K} |\hat{\psi}_j^{(\ell)}(\omega)|^2 < \varepsilon,$$

for all $\ell = 1, \ldots, 2^d - 1$.  

In particular we want to construct an orthonormal basis. In this sense, let \( \mathcal{E} := M[0, 1]^d \cap \mathbb{Z}^d \) and \( \mathcal{E}_0 := \mathcal{E} \setminus \{0\} \) we observe:

\[
\sigma_j(\omega) = \sigma_{j+1}(\omega) + \sum_{\ell=1}^{2^d-1} \sigma_{j+1}(\omega + 2^{j+1} \pi \theta_{\ell}), \quad \theta_{\ell} \in \mathcal{E}_0.
\]

In order to have orthogonality:

- respect to \( \ell = 1, \ldots, 2^d - 1 \) with \( j \) fixed

\[
\sum_{\gamma \in \mathcal{E}} \frac{e^{-i \langle \pi \gamma, \eta(\ell) - \eta(m) \rangle}}{\sigma_j(\omega)} \sqrt{\sigma_{j+1}(\omega + 2^{j+1} \pi (\theta_{\ell} + \gamma)) \sigma_{j+1}(\omega + 2^{j+1} \pi (\theta_m + \gamma))} = \delta_{\ell, m},
\]

- between \( \mathcal{W}_{j-1} \) and \( \mathcal{W}_j \)

\[
\sum_{\gamma \in \mathcal{E}} e^{i \langle \pi \gamma, \eta(\ell) \rangle} \sqrt{\sigma_{j+1}(\omega + 2^{j+1} \pi (\theta_{\ell} + \gamma)) \sigma_{j+1}(\omega + 2^{j+1} \pi \gamma)} = 0.
\]

should be satisfied for \( \eta : \{1, \ldots, 2^d - 1\} \rightarrow \mathcal{E}_0 \), an opportune permutation of the representative of cosets in \( \mathcal{E}_0 \).
In two dimensions we consider the functions

$$\hat{\psi}_j^{(\ell)}(\omega) = 2^{-j-1} e^{-i2^{-j-1}\omega,\eta(\ell)} \sqrt{\frac{\sigma_{j+1}(\omega + 2^{j+1}\pi\theta_\ell)}{\sigma_j(\omega)}} \hat{\psi}(\omega)$$

where

$$\begin{align*}
1 & \mapsto \theta_1 = (1, 0)^t \\
\eta : 2 & \mapsto \theta_3 = (1, 1)^t \\
3 & \mapsto \theta_2 = (0, 1)^t
\end{align*}$$

We proved that

$$\{\psi_j^{(\ell)}(\cdot - 2^{-j}k), \ k \in \mathbb{Z}^2, j \in \mathbb{Z}, \ell = 1, 2, 3\}$$

are an orthonormal basis for $\bigoplus_{j \in \mathbb{Z}} W_j$. 

Wavelet basis in $d = 2$
